

GROUP 5 | Phase 2 Wrap-Up Document

The Computer Science MAZE GAME

Overview of the Game:

- The game you will be playing is a puzzle game in which you (the player) will collect letters and other characters found on a standard keyboard to fill out words to complete/solve a riddle. These letters and characters will be randomly placed on a grid-like structure moving around you (the player) for you to collect. Your movement is
 - These riddles are based upon technical information pertaining to the grade 12 and 11 computer science courses at John Fraser Secondary School.
 - For example, fill in the blank: "I start with // and I'm ignored, what am I? Answer: _____" (Correct answer: "comment")
 - There are multiple rounds/difficulties, which you (the player) will advance through during your playtime.
- **Existing features:**
 - Procedurally generated maze with randomized letter positions
 - Player movement throughout the maze; the maze moves around the player, NOT the other way around.
 - Retrieval of randomized (computer science related) words from the Wordnik API, including their respective definitions.

- Syllables, phonings (proper pronunciation) and parts of speech classifications (nouns, verbs, etc.) retrieved from RiTa
- Custom player sprite with animated direction dependent movement.

An Improvement Section:

- Current issues:
 - Difficulties fully utilizing the Wordnik API:
 - loadJSON() was not working properly, an API error was printed to the console.
 - Word definitions are still not located in the right place; currently overlap with the generating maze.
 - **SOLUTION(S):**
 - To solve the loadJSON() problem, we could use the fetch() function which leads to the data loading properly.
 - Incomplete Maze Wall implementation:
 - Difficulties regarding the mathematical process of generating the maze around the letters (fully enclosed, with all paths possible).
 - **SOLUTION(S):**
 - To spend more time working/finalizing the mathematical process, and creating a definite plan of action.
 - Incomplete/Unfinished UI:
 - The current UI is very basic; there was no time to implement a new UI with a cleaner look, better color choices, etc.
 - **SOLUTION(S):**

- To create another definite plan of action to design the UI.
A drawn out UI (on a piece of paper) would suffice and help finalize the design.

A Team Overview:

- **James (Tester):**

- Was responsible for writing the vast majority of the code:
 - On the 5th day (1st day of the 2nd phase) he finalized the full gameManager class, and created a new class to retrieve player positional data for class inheritance.
 - On the subsequent days, he implemented the RiTa library to further add additional features to the game, alongside generating words and their definitions from Wordnik.

- **Andrew (Documenter):**

- Was mainly responsible for the explanation and design of the game:
 - On the 7th day, he wrote and created the full user guide that explains how the game works; he additionally also adjusted the user's guide and information.
 - On the final day (8th day) he created the full Wrap-Up document (which is what you are reading).
 - Also responsible for a lot of the full documentation of the code.

- **Tarun (Project Manager):**

- Was responsible for managing the team; keeping everyone on task:
 - He was responsible for a lot of ideas regarding the game itself, alongside helping with documentation.

- Kept a lot of information from everyone and their actions throughout each day (as a proper project manager should), and helped everyone know their daily tasks.

- **Iat Seng (Designer):**

- Responsible for finalizing a lot of ideas and the code:
 - He collaborated and worked with Andrew to review all the methods that were used in the previous phase of the Project Management on days 5 and 6.
 - Worked on the documentation and application of the code on day 7 (also was responsible for creating the rubric that day).

- **Max (Lead Developer):**

- Responsible for helping spot bugs in the code and to help with the implementation (alongside James) of the API and library:
 - Mainly, on day 6, the group ran into issues regarding the Wordnik API which Max helped solve by searching for a solution online.
 - On day 7, he contributed to the idea of using the sprite animation and to add additional features to the game
